## Hash Function

- Also known as Message Digest
- it is a function that takes an input message and produce an output (hash value, or message digest)
- the input can be a variable-length bit string, the output is a fixed-length bit string (e.g. 128 bits)
- It is a one-way function
  - it is not practical to figure out which input corresponds to a given output

$$h=H(m)$$

- e.g. MD2, MD5 (RFC1321), SHA-1, SHA-2

2

## Hash function properties

- Il messaggio  $m$  in ingresso può essere di qualsiasi lunghezza
- Il messaggio  $h$  in uscita ha sempre lunghezza fissa
- La trasformazione  $H(m)$  è monodirezionale (one-way)
- Riduce le dimensioni del messaggio, riassumendo le caratteristiche di un messaggio
  - permette rilievo di eventuali alterazioni
- La computazione  $h=H(m)$  è veloce e poco onerosa
- The message digest should look “randomly generated”
- It must be computationally infeasible to find a message with a given prespecified message digest
- It should be impossible to two find two messages that has the same digest (although the function is not one-to-one)

## How many bits should the output have?

- How many bits should the output have in order to prevent someone from being able to find two message with the same hash?
- If the message digest has  $m$  bits, then it would take  $2^{m/2}$  messages chosen at random (Birthday Paradox)
  - this is why message digest functions have output of at least 128 bits (in place of just 64 as for symmetric cryptography)
  - however sometime it is not sufficient for an attacker to find out just two messages with the same hash; in such case, a brute-force attack requires  $2^m$  searches

## About the hash function

- Message digest functions are like alchemy
  - It's a bunch of steps that each mangle the message more and more
  - A plausible way of constructing a message digest function is to combine lots of "perverse" operations
  - however the message digest should remain easy to compute
- Often, hash function uses constants (magic numbers)
  - Often the algorithm designers specify how they chose a particular number (to prevent suspects on particular properties of the chosen number)
    - $\pi$
    - Published books with random numbers  
(A book has been published in 1939)

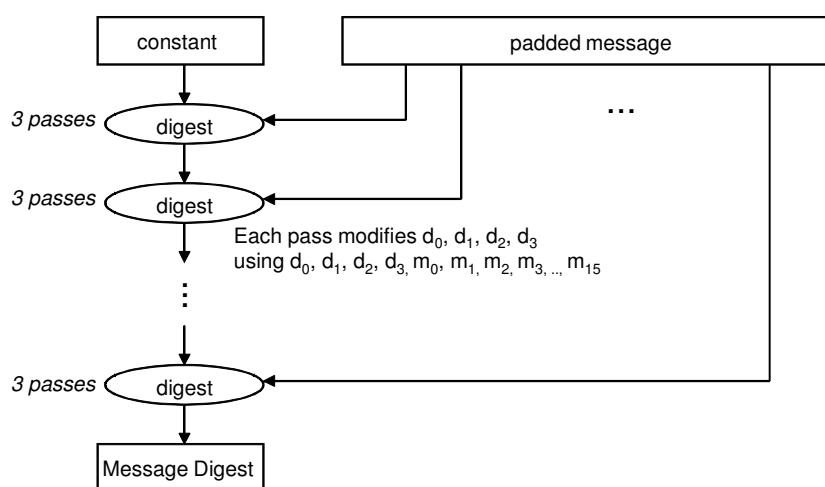

5

## MD4

- Designed by Ronald L. Rivest of MIT
- Can handle message with an arbitrary number of bits
- Produce a 128 bit hash
  - 32-bit-world-oriented (instead of byte oriented schemes like MD2)
- Message padding
  - the message must be a multiple of 512bits (16 words);
  - the message is padded by adding one "1" bit and
  - padded with "0"s until bit  $N \times 512 - 64$
  - the remaining 64 bit represent the number of unpadded message bits, mod  $2^{64}$
- Message processed in 512-bit blocks (16 words)
- Each step makes three passes over the message block
- Message digest computed on 128-bit quantity (4 words)

6

## MD4 scheme

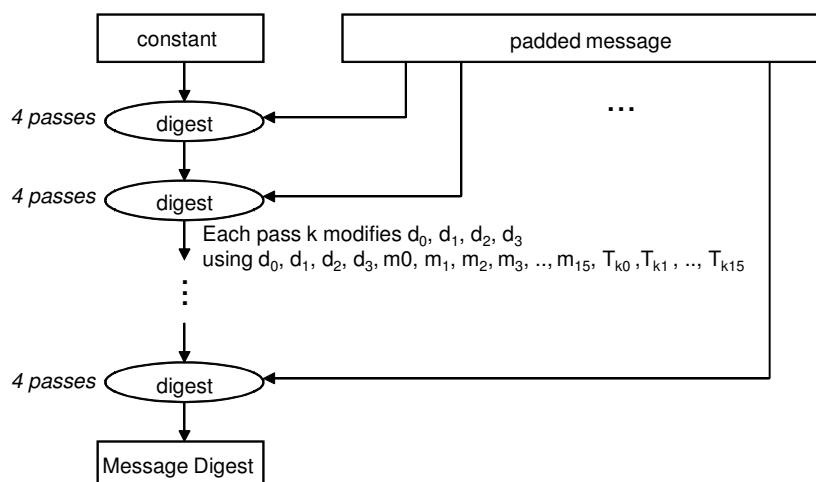

7

## MD5

- Designed to be less concerned with speed and more with security, respect to MD4
- Very similar to MD4:
  - can handle message with an arbitrary number of bits
  - produces a 128 bit hash
  - 32-bit-world oriented (it works on 4 x 32-bit-worlds)
  - message processed in 512-bit blocks (16 words)
  - message padding
- The main differences are:
  - 4 passes over each 128-bit (16-byte/4-word) chunk
  - different functions
  - uses a different constant  $T$  for each message word for each pass (4 passes x 16 message words = 64 32-bit constants)

8

## MD5 scheme

9

## MD5 initialization

- Padding

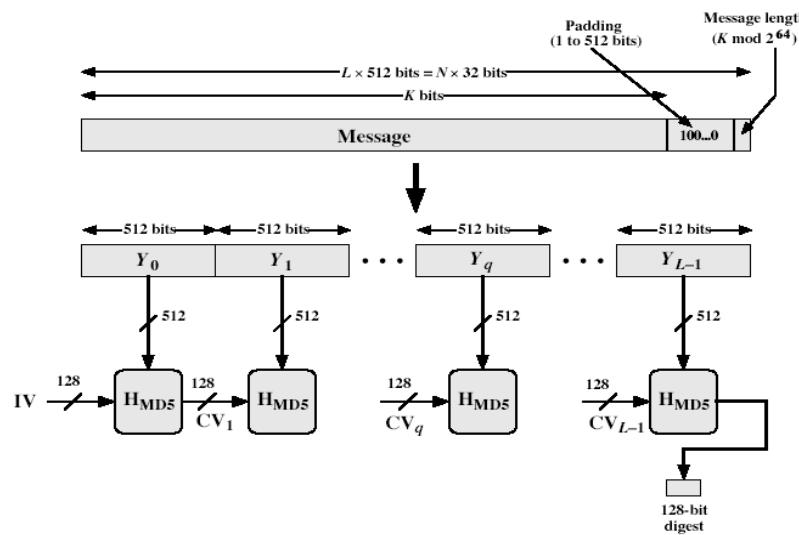

- il messaggio viene sempre completato con bit di riempimento in modo in modo che la lunghezza modulo 512 sia 448 bit
  - ovvero una lunghezza multipla di 512 meno 64 bit
  - a questo scopo vengono aggiunti da 1 a 512 bit
  - i bit di riempimento sono un 1 seguito da zeri
- vengono aggiunti 64 bit (512-448) in cui viene inserita la lunghezza del messaggio modulo  $2^{64}$ 
  - ottenendo così una stringa di lunghezza multipla di 512

- Inizializzazione del buffer MD di 128 bit composto da 4 word da 32 bit (A, B, C, D) prefissati

- A= 01 23 45 67
- B= 89 AB CD EF
- C= FE DC BA 98
- D= 76 54 32 10

10

## MD5 padding

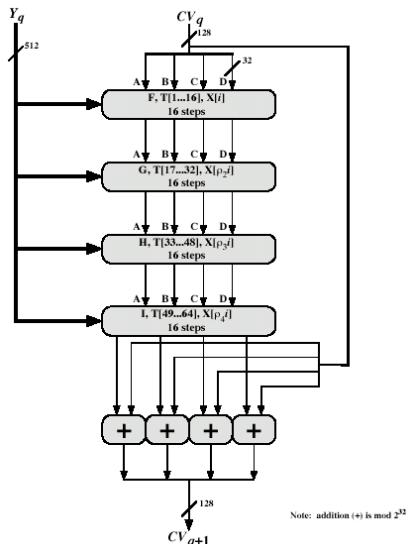

11

## MD5 processing

- Elaborazione del messaggio in blocchi da 512 bit (16 word)
- A partire dal buffer iniziale, per ogni blocco si effettuano 4 fasi di elaborazione
- In ognuna di esse viene eseguita 1 funzione differente, indicata rispettivamente con F, G, H e I
- Ciascuna fase utilizza in ingresso
  - il buffer ABCD da 128 bit,
  - il blocco corrente  $Y_q$  da 512 bit,
  - 1/4 di una tabella di 64 valori  $T[1..64]$  basati sulla funzione seno (valori tabellati)
- l'uscita della quarta fase viene sommata word a word con l'ingresso (somma modulo 32)
- l'uscita dell'ultima elaborazione è il message digest finale

12

## MD5 processing

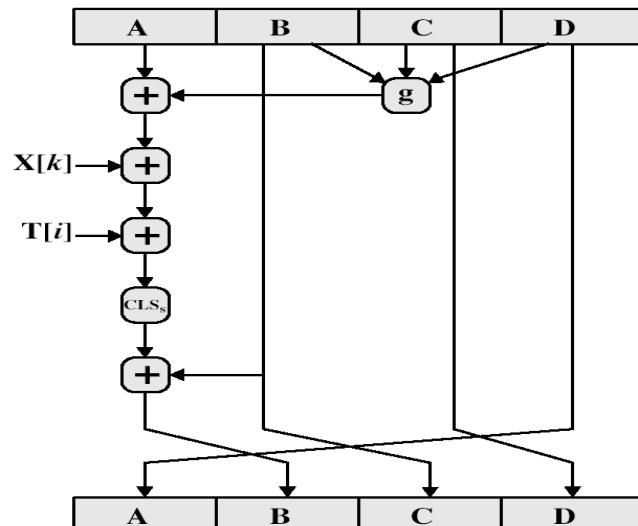

13

## MD5 processing (4 passes)

- $A = B + ((A + g(B, C, D) + X[k] + T[i]) \ll s)$
- Pass 1  
 $g(x, y, z) = F(x, y, z) = (x \wedge y) \vee (\neg x \wedge z)$
- Pass 2  
➢  $G(x, y, z) ..$
- Pass 3 ...  
➢  $H(x, y, z) ..$
- Pass 4 ...  
➢  $I(x, y, z) ..$

14

## MD5 processing (16 steps)

15

## Secure Hash Standard (SHS/SHA)

- Set of cryptographically secure hash algorithms specified by NIST as message digest functions
- The original specification of the algorithm was published in 1993 as the Secure Hash Standard, FIPS PUB 180, by NIST (SHA-0)
  - **Secure Hash Algorithm (SHA)**
- Successively revised by the following standards
  - **SHA-1, SHA-224, SHA-256, SHA-384, and SHA-512**
  - the latter four variants are sometimes collectively referred to as **SHA-2**
  - **SHA-1 (and SHA)** produces a message digest that is 160 bits long
  - the other algorithms produce digests that are respectively 224, 256, 384, 512 bits long
- SHA-1 is employed in several widely used security applications and protocols
  - **TLS/SSL, PGP, SSH, S/MIME, IPsec, etc.**

16

## SHA standards

Algoritmo e variante	Dimensione dell'output (bit)	Dimensione dello stato interno (bit)	Dimensione del blocco (bit)	Max. dimensione del messaggio (bit)	Dimensione della word (bit)
SHA-0	160	160	512	$2^{64} - 1$	32
SHA-1	160	160	512	$2^{64} - 1$	32
SHA-2	SHA-256/224	256	512	$2^{64} - 1$	32
	SHA-512/384	512	1024	$2^{128} - 1$	64

17

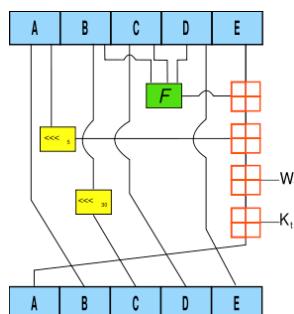

## SHA-1

- SHA-0 was superseded by the revised version SHA-1, published in 1995
  - SHA-1 differs from SHA-0 only by a single bitwise rotation in the message schedule of its compression function
  - this was done, according to the NSA, to correct a flaw in the original algorithm which reduced its cryptographic security
- SHA-1 (as well as SHA-0) produces a 160-bit (5-word blocks) digest from a message with a maximum length of ( $2^{64} - 1$ ) bits
  - not a problem, since it would take several hundred years to transmit at 10Gb/s and it would take even longer (hundreds of centuries) to compute SHA-1 at 100MIPS

18

## SHA-1 (cont.)

- Based on principles similar to those used by MD5 message digest algorithms Pad the message as in MD5 (except that the message is limited to  $2^{64}$  bits)
- Operates in stages (as MD5)
  - Makes 5 passes for each block of data (4 in MD5)
  - Uses a different 160-bit mangle function in each stage

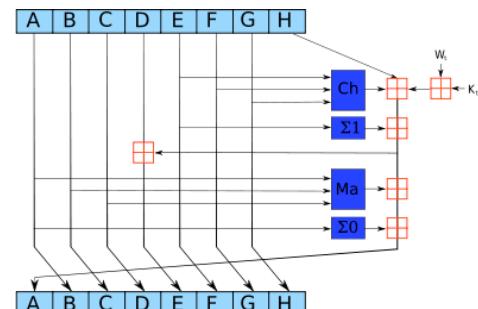

- Little slower than MD5 and (presumably) little more secure

19

## SHA-2

- SHA-224, SHA-256, SHA-384, and SHA-512
  - FIPS PUB 180-2 standard in 2002 (SHA-224 variant in 2004)
- SHA-256 and SHA-512 are computed with 32- and 64-bit words, respectively
  - use different shift amounts and additive constants
  - different number of rounds
- SHA-224 and SHA-384 are simply truncated versions of the first two, computed with different initial values

20

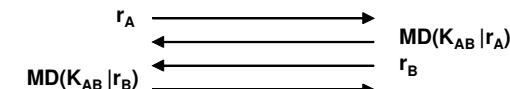

## Future of SHA

- SHA-1 has been compromised
- SHA-2 security is not yet as well-established
  - **not received as much scrutiny as SHA-1**
  - **although no attacks have yet been reported, SHA-2 is algorithmically similar to SHA-1**
- An open competition for a new SHA-3 function has been started by NIST on November 2, 2007
  - **similar to the development process for AES**
  - **submissions was due October 31, 2008**
  - **the proclamation of a winner and publication of the new standard are scheduled to take place in 2012**

21

## What doing with a Hash

- Password Hashing
  - **a system may know/store just the hash of a passwd**
- Message fingerprint
  - **maintaining a copy of a message digest of some data/program in place of the copy of the entire data (for integrity check)**
- Digital signature
  - **Signing the MD of a message instead of the entire message**
    - for efficiency (MDs are easier to compute than public-key algorithms)
- Authentication
  - **similar to secret key cryptography**

22

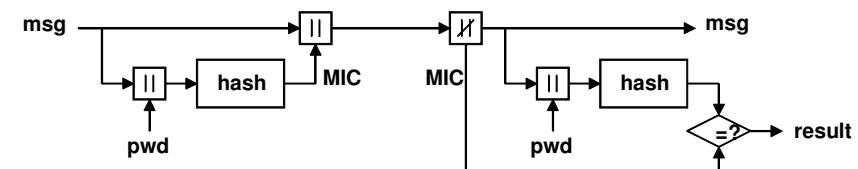

## What doing with a Hash

- Encryption
  - **encryption should be easy with MD, but what about decryption? ;-**
  - **one-time pad**
    - just as OFB, generating a pseudorandom bit stream and encrypting the message just by a simple  $\oplus$
    - the pseudorandom stream is generated starting from a MD of a secret:  $b_1 = \text{MD}(K_{AB} | IV)$ ,  $b_2 = \text{MD}(K_{AB} | b_1)$ , ...,  $b_{k+1} = \text{MD}(K_{AB} | b_k)$
    - same problems as OFB
  - **mixing in the plaintext**
    - as in CFB, the plaintext is mixed in the bit stream generation
    - $b_1 = \text{MD}(K_{AB} | IV)$ ,  $b_2 = \text{MD}(K_{AB} | c_1)$ , ...,  $b_{k+1} = \text{MD}(K_{AB} | c_k)$
    - $c_1 = m_1 \oplus b_1$ ,  $c_2 = m_2 \oplus b_2$ , ...,  $c_k = m_k \oplus b_k$

23

## What doing with a Hash

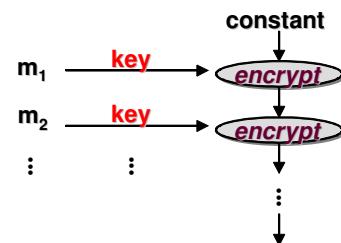

- Computing a MIC (Message Integrity Check) or MAC
  - **the obvious thought is that  $\text{MD}(m)$  is a MIC for  $m$ , but it isn't; anyone can compute  $\text{MD}(m)$**
  - **the way is to send also a (shared) secret**
    - if the secret is put at the beginning ( $\text{MD}(K, m)$ ), such MD algorithm might become weak since the attacks may continue the MD computation adding a padding
    - however putting the secret at the end might expose the secret
    - a solution could be sending just one half of the hash

24

## Using secret key algorithm as Hash Function

- A hash algorithm can be replaced by a block ciphers
    - using  $H_0=0$  and zero-pad of final block
    - compute:  $H_i = E_{Mi}[H_{i-1}]$
    - and use final block as the hash value
    - similar to CBC but without a key
  - resulting hash can be too small (64-bit)
  - not very fast to compute

## Using secret key algorithm as Hash Function

- Example: the original UNIX password hash (crypt function)
    - first convert the passwd (the message) into a secret key
      - the 7bit ASCII codes of the first 8 chars form the 56bit key
    - the key is used to encrypt the number 0 with a modified DES
      - 25 DES passes are performed
      - the modified DES is used to prevent HW accelerators designed to DES to be used to reverse the passwd hash
      - the modified algorithm uses a 12-bit random number (salt)
    - the salt and the final ciphertext are base64-encoded into a printable string stored in the password or shadow file
  - Currently, the most common crypt function used by Unix/Linux systems supports both the original DES-based and hash-based algorithms (e.g. MD5-crypt function), where common hash function such as MD5 or SHA-1 are used
    - such functions generally allow users to have any length password (> 8bytes), and do not limit the password to ASCII (7-bit) text

# Unix password hashing

- The MD5-crypt function is really not a straight implementation of MD5
    - first the password and salt are MD5 hashed together in a first digest
    - then 1000 iteration loops continuously remix the password, salt and intermediate digest values
    - the output of the last of these rounds is the resulting hash
  - A typical output of the stored password together with username, salt, and other information is:

alice:\$1\$BZftq3sP\$xEeZmr2fGEnKjVAxziQo68:12747:0:99999:7:::

- where \$1\$ indicates the use of MD5-crypt, while BZftq3sP is the base-64 encoding of the salt and xEeZmr2fGEnKjVAxzjQo68 is the password hash

## Message Authentication (data origin authentication, integrity check)

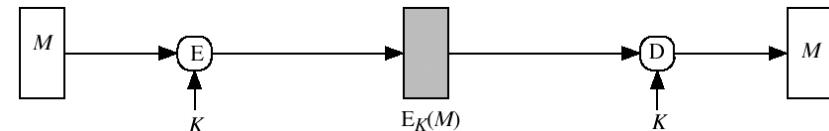

## Message Authentication

- Message authentication is concerned with:
  - protecting the integrity of a message
  - validating identity of originator
  - non-repudiation of origin (dispute resolution)
  
- Three alternative approaches:
  - use of secret or public key encryption algorithms
  - use of encryption and hash algorithms
  - use of ad-hoc (secret key based) Message Authentication Code (MAC) algorithms

29

## Msg. Auth. - Secret-key Encryption

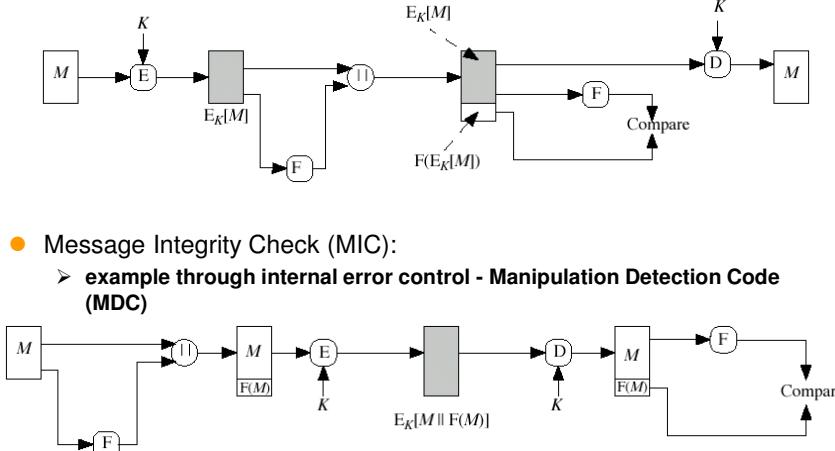

- Symmetric encryption:
  - encryption provides both confidentiality and origin authentication
  - however, need to recognize corrupted messages (MIC)

30

## Msg. Auth. - Secret-key Encryption + Hash

- External error control (checksum):
  - does not securely protect the integrity
  
- Message Integrity Check (MIC):
  - example through internal error control - Manipulation Detection Code (MDC)

31

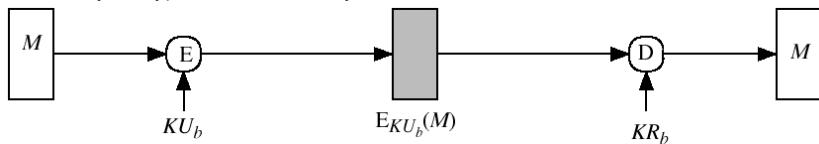

## Msg. Auth. - Asymmetric Cryptography

- if public-key encryption is used
  - encryption with public key provides no proof of sender (no sender authentication)
    - since anyone potentially knows public-key
  - both secrecy and authentication if
    - sender “signs” message using their private-key
    - then encrypts with recipients public key
  - problems
    - the result is the same cost of two public-key encryption
    - need to recognize corrupted messages for integrity check

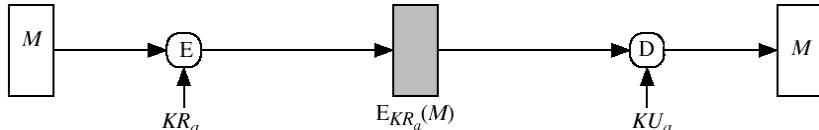

32

## Msg. Auth. - Asymmetric Cryptography (cont.)

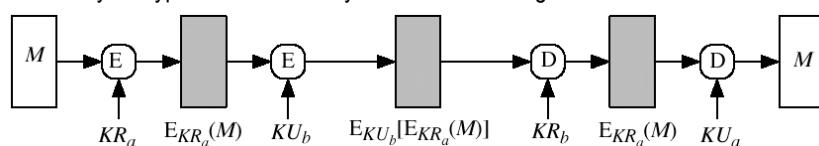

Public-key encryption: confidentiality

Public-key encryption: authentication/signature

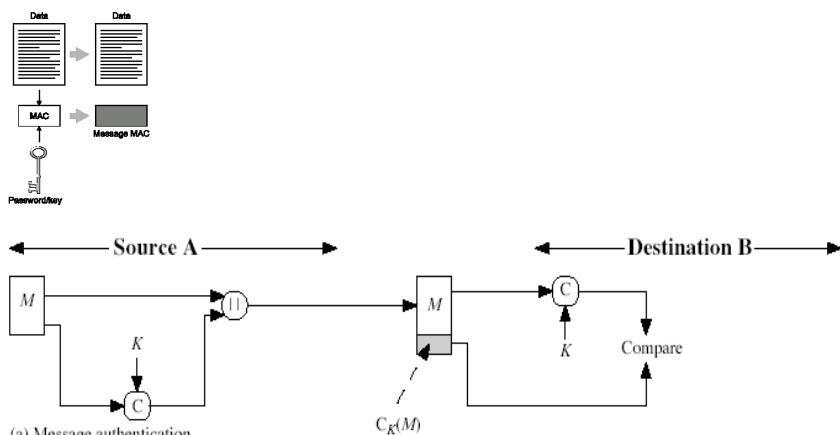

Public-key encryption: confidentiality + authentication/signature

33

## Message Authentication Code (MAC)

34

## Message Authentication Code (MAC)

- a MAC is a cryptographic checksum, generated by an algorithm that creates a small fixed-sized block
  - depending on both message and a secret key K
    - $\text{MAC} = \text{C}_K(\text{M})$
  - condenses a variable-length message M to a fixed-sized authenticator
    - it need not be reversible
    - is a many-to-one function
      - potentially many messages have same MAC
      - but finding these needs to be very difficult
- appended to message as a **signature**
- receiver performs same computation on message and checks it matches the MAC
- provides assurance that message is unaltered and comes from sender

35

## Message Authentication Code (cont.)

- In case secrecy is also required
  - use of encryption with separate key
  - can compute MAC either before or after encryption
  - is generally regarded as better done before
- why use a MAC?
  - sometimes only authentication is needed
  - sometimes need authentication to persist longer than the encryption (eg. archival use)
- MAC is similar but not equal to digital signature

36

## Requirements for MACs

- MAC functions have to satisfy the following requirements:
  - knowing a message and MAC, is infeasible to find another message with same MAC
  - MACs should be uniformly distributed
  - MAC should depend equally on all bits of the message

## Using Symmetric Ciphers for MACs

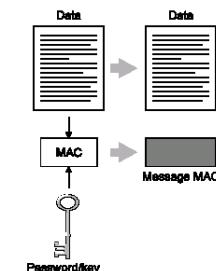

- Can use any block cipher chaining mode and use final block as a MAC
- Data Authentication Algorithm (DAA) is a widely used MAC based on DES-CBC
  - using IV=0 and zero-pad of final block
  - encrypt message using DES in CBC mode
  - and send just the final block as the MAC
    - or the leftmost M bits of final block
- But final MAC is now too small for security ( $\leq 64$ bit)

## MAC Security

- Cryptanalytic attacks
  - like block ciphers, brute-force attacks are the best alternative
- Transient effect
  - message authentication, as opposed to encryption, has a "transient" effect
  - a published breaking of a message authentication scheme would lead to the replacement of that scheme, but would have no adversarial effect on information authenticated in the past
  - this is in contrast with encryption, where information encrypted today may suffer from exposure in the future if, and when, the encryption algorithm is broken

## Hash Message Authentication Code (H-MAC)

- H-MAC (RFC2104)  
è l'applicazione di una funzione di hash in combinazione con una chiave segreta: solo chi possiede la chiave può generare l'hash

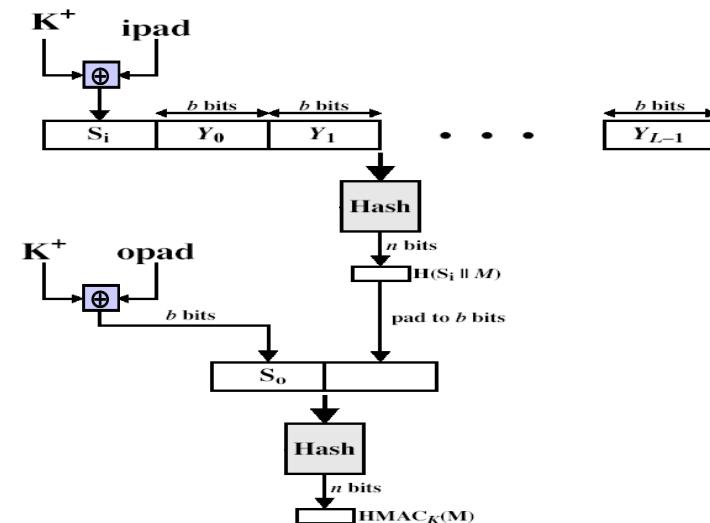

## HMAC

- Specified as Internet standard RFC2104
- Uses hash function on the message:

$$\text{HMAC}_K = \text{Hash}[(K^+ \text{ XOR } \text{opad}) \parallel \text{Hash}[(K^+ \text{ XOR } \text{ipad}) \parallel M]]$$

where  $K^+$  is the key padded out to size  
and opad, ipad are specified padding constants

- Overhead is just 3 more hash calculations than the message needs alone
- Any of MD5, SHA-1, RIPEMD-160 can be used

41

42

## Truncated HMAC

- A well-known practice with MACs is to truncate the output of the MAC and output only part of the bits
  - advantages: less information on the hash result available to an attacker**
  - disadvantages less bits to predict for the attacker**
- It is recommended to let the output length  $t$  be not less than half the length of the hash output and not less than 80 bits
- Sometimes HMAC that uses a hash function  $H$  with  $t$  bits of output is denoted as  $\text{HMAC}-H-t$ 
  - example,  $\text{HMAC-SHA1-80}$  denotes HMAC computed using the SHA-1 function and with the output truncated to 80 bits**

43
